

I'm biased but I feel super confident saying that the best way to learn Python and get hired as efficiently as possible is to follow the exact steps I've outlined in our [Python Developer Career Path](#).

Give it a try. You won't regret it 😎.

Otherwise, please enjoy this guide and if you'd like to submit any corrections or suggestions, feel free to email us at support@zerotomastery.io

Numbers

Python's 2 main types for Numbers is int and float (or integers and floating point numbers)

```
type(1)      # int
type(-10)    # int
type(0)      # int
type(0.0)    # float
type(2.2)    # float
type(4E2)    # float - 4*10 to the power of 2
```

```
# Arithmetic
10 + 3      # 13
10 - 3      # 7
10 * 3      # 30
10 ** 3     # 1000
10 / 3      # 3.3333333333333335
10 // 3     # 3 --> floor division - no decimals and returns an integer
10 % 3      # 1 --> modulo operator - return the remainder. Good for checking if a number is even or odd
```

```
# Basic Functions
pow(5, 2)    # 25 --> like doing 5**2
abs(-50)     # 50
round(5.46)  # 5
round(5.468, 2) # 5.47 --> round to nth digit
```

```
bin(512)      # '0b1000000000' --> binary format
hex(512)      # '0x200' --> hexadecimal format
```

```
# Converting Strings to Numbers
age = input("How old are you?")
age = int(age)
pi = input("What is the value of pi?")
pi = float(pi)
```

Strings

Strings in python are stored as sequences of letters in memory

```
type('Helllloooooo') # str

'I\'m thirsty'
"I'm thirsty"
"\n" # new line
"\t" # adds a tab

'Hey you!'[4] # y
name = 'Andrei Neagoie'
name[4]      # e
name[:]      # Andrei Neagoie
name[1:]     # ndrei Neagoie
name[:1]     # A
name[-1]     # e
name[::-1]   # eirdeN iogaenA
name[::-1]   # eiogaen ierdnA
name[0:10:2] # Ade e
# : is called slicing and has the format [ start : end : st

'Hi there ' + 'Timmy' # 'Hi there Timmy' --> This is called concatenation
'*'*10 # *****
```

```
# Basic Functions
len('turtle') # 6
```

```
# Basic Methods
' I am alone '.strip()      # 'I am alone' --> Strips leading and trailing spaces
'On an island'.strip('d')    # 'On an islan' --> Strips 'd' from both ends
'but life is good!'.split()  # ['but', 'life', 'is', 'good!']
'Help me'.replace('me', 'you') # 'Help you' --> Replace 'me' with 'you'
'Need to make fire'.startswith('Need') # True
'and cook rice'.endswith('rice')      # True
'bye bye'.index('e')                   # 2
'still there?'.upper()                  # STILL THERE?
'HELLO?!'.lower()                      # hello?!
'ok, I am done.'.capitalize()          # 'Ok, I am done.'
'oh hi there'.find('i')                 # 4 --> returns the index of the first occurrence
'oh hi there'.count('e')                 # 2
```

```
# String Formatting
name1 = 'Andrei'
name2 = 'Sunny'
print(f'Hello there {name1} and {name2}')      # Hello the
print('Hello there {} and {}'.format(name1, name2)) # Hello
print('Hello there %s and %s' %(name1, name2)) # Hello the
```

```
#Palindrome check
word = 'reviver'
p = bool(word.find(word[::-1]) + 1)
print(p) # True
```

Boolean

True or False. Used in a lot of comparison and logical operations in Python

```
bool(True)
bool(False)

# all of the below evaluate to False. Everything else will
print(bool(None))
print(bool(False))
print(bool(0))
print(bool(0.0))
print(bool([]))
print(bool({}))
print(bool(()))
print(bool(''))
print(bool(range(0)))
print(bool(set()))

# See Logical Operators and Comparison Operators section for
```

Lists

Unlike strings, lists are mutable sequences in python

```
my_list = [1, 2, '3', True] # We assume this list won't mutate
len(my_list)                # 4
my_list.index('3')          # 2
my_list.count(2)             # 1 --> count how many times 2 appears

my_list[3]                   # True
my_list[1:]                  # [2, '3', True]
my_list[:1]                  # [1]
my_list[-1]                  # True
```

```

my_list[::1]          # [1, 2, '3', True]
my_list[::-1]         # [True, '3', 2, 1]
my_list[0:3:2]        # [1, '3']

```

: is called slicing and has the format [start : end : step]

```

# Add to List
my_list * 2           # [1, 2, '3', True, 1, 2, '3', True]
my_list + [100]       # [1, 2, '3', True, 100] --> does not mutate
my_list.append(100)    # None --> Mutates original list
my_list.extend([100, 200]) # None --> Mutates original list
my_list.insert(2, '!!!') # None --> [1, 2, '!!!', '3', True]

# Join lists
' '.join(['Hello', 'There']) # 'Hello There' --> Joins elements

```

```

# Copy a List
basket = ['apples', 'pears', 'oranges']
new_basket = basket.copy()
new_basket2 = basket[:]

```

```

# Remove from List
[1,2,3].pop()         # 3 --> mutates original list, default index
[1,2,3].pop(1)        # 2 --> mutates original list
[1,2,3].remove(2)     # None --> [1,3] Removes first occurrence
[1,2,3].clear()       # None --> mutates original list and removes all
del [1,2,3][0]         #

```

```

# Ordering
[1,2,5,3].sort()       # None --> Mutates list to [1, 2, 3, 5]
[1,2,5,3].sort(reverse=True) # None --> Mutates list to [5, 3, 2, 1]
[1,2,5,3].reverse()    # None --> Mutates list to [3, 5, 2, 1]
sorted([1,2,5,3])      # [1, 2, 3, 5] --> new list created
list(reversed([1,2,5,3])) # [3, 5, 2, 1] --> reversed() returns iterator

```

```

# Useful operations
1 in [1,2,5,3]         # True
min([1,2,3,4,5])       # 1
max([1,2,3,4,5])       # 5
sum([1,2,3,4,5])       # 15

```

```

# Get First and Last element of a list
mList = [63, 21, 30, 14, 35, 26, 77, 18, 49, 10]
first, *x, last = mList
print(first) #63
print(last) #10

```

```
# Matrix
matrix = [[1,2,3], [4,5,6], [7,8,9]]
matrix[2][0] # 7 --> Grab first first of the third item in

# Looping through a matrix by rows:
mx = [[1,2,3], [4,5,6]]
for row in range(len(mx)):
    for col in range(len(mx[0])):
        print(mx[row][col]) # 1 2 3 4 5 6

# Transform into a list:
[mx[row][col] for row in range(len(mx)) for col in range(len(mx[0]))]

# Combine columns with zip and *:
[x for x in zip(*mx)] # [(1, 3), (2, 4)]
```

```
# List Comprehensions
# new_list[<action> for <item> in <iterator> if <some condition>]
a = [i for i in 'hello'] # ['h', 'e', 'l', 'l', 'o']
b = [i*2 for i in [1,2,3]] # [2, 4, 6]
c = [i for i in range(0,10) if i % 2 == 0] # [0, 2, 4, 6, 8, 10]
```

```
# Advanced Functions
list_of_chars = list('Helloooo')
sum_of_elements = sum([1,2,3,4,5])
element_sum = [sum(pair) for pair in zip([1,2,3], [4,5,6])]
sorted_by_second = sorted(['hi', 'you', 'man'], key=lambda el: el[1])
sorted_by_key = sorted([
    {'name': 'Bina', 'age': 30},
    {'name': 'Andy', 'age': 18},
    {'name': 'Zoey', 'age': 55}],
    key=lambda el: (el['name'])) # [{'name': 'Andy', 'age': 18}, {'name': 'Bina', 'age': 30}, {'name': 'Zoey', 'age': 55}]
```

```
# Read line of a file into a list
with open("myfile.txt") as f:
    lines = [line.strip() for line in f]
```

Dictionaries

Also known as mappings or hash tables. They are key value pairs that are guaranteed to retain order of insertion starting from Python 3.7

```
my_dict = {'name': 'Andrei Neagoie', 'age': 30, 'magic_power': 100}
my_dict['name'] # Andrei Neagoie
len(my_dict) # 3
list(my_dict.keys()) # ['name', 'age', 'magic_power']
list(my_dict.values()) # ['Andrei Neagoie', 30, 100]
```

```
list(my_dict.items())           # [('name', 'Andrei Nea
my_dict['favourite_snack'] = 'Grapes'# {'name': 'Andrei Nea
my_dict.get('age')              # 30 --> Returns None
my_dict.get('ages', 0 )         # 0 --> Returns default
```

```
#Remove key
del my_dict['name']
my_dict.pop('name', None)
```

```
my_dict.update({'cool': True})
{**my_dict, **{'cool': True} }
new_dict = dict(['name', 'Andrei'], ['age', 32], ['magic_power', 10])
new_dict = dict(zip(['name', 'age', 'magic_power'], ['Andrei', 32, 10]))
new_dict = my_dict.pop('favourite_snack')
```

```
# Dictionary Comprehension
{key: value for key, value in new_dict.items() if key == 'age'}
```

Tuples

Like lists, but they are used for immutable things (that don't change)

```
my_tuple = ('apple', 'grapes', 'mango', 'grapes')
apple, grapes, mango, grapes = my_tuple# Tuple unpacking
len(my_tuple)                       # 4
my_tuple[2]                         # mango
my_tuple[-1]                       # 'grapes'
```

```
# Immutability
my_tuple[1] = 'donuts' # TypeError
my_tuple.append('candy')# AttributeError
```

```
# Methods
my_tuple.index('grapes') # 1
my_tuple.count('grapes') # 2
```

```
# Zip
list(zip([1,2,3], [4,5,6])) # [(1, 4), (2, 5), (3, 6)]
```

```
# unzip
z = [(1, 2), (3, 4), (5, 6), (7, 8)] # Some output of zip()
```

```
unzip = lambda z: list(zip(*z))
unzip(z)
```

Sets

Unordered collection of unique elements.

```
my_set = set()
my_set.add(1) # {1}
my_set.add(100) # {1, 100}
my_set.add(100) # {1, 100} --> no duplicates!

new_list = [1,2,3,3,3,4,4,5,6,1]
set(new_list) # {1, 2, 3, 4, 5, 6}

my_set.remove(100) # {1} --> Raises KeyError if element not in set
my_set.discard(100) # {1} --> Doesn't raise an error if element not in set
my_set.clear() # {}
new_set = {1,2,3}.copy() # {1,2,3}
```

```
set1 = {1,2,3}
set2 = {3,4,5}
set3 = set1.union(set2) # {1,2,3,4,5}
set4 = set1.intersection(set2) # {3}
set5 = set1.difference(set2) # {1, 2}
set6 = set1.symmetric_difference(set2) # {1, 2, 4, 5}
set1.issubset(set2) # False
set1.issuperset(set2) # False
set1.isdisjoint(set2) # False --> return True if no elements in common
```

```
# Frozenset
# hashable --> it can be used as a key in a dictionary or as an element in a set
<frozenset> = frozenset(<collection>)
```

None

None is used for absence of a value and can be used to show nothing has been assigned to an object

```
type(None) # NoneType
a = None
```

Comparison Operators

```

==          # equal values
!=          # not equal
>           # left operand is greater than right operand
<           # left operand is less than right operand
>=          # left operand is greater than or equal to right operand
<=          # left operand is less than or equal to right operand
<element> is <element> # check if two operands refer to same object

```

Logical Operators

```

1 < 2 and 4 > 1 # True
1 > 3 or 4 > 1  # True
1 is not 4      # True
not True        # False
1 not in [2,3,4] # True

if <condition that evaluates to boolean>:
    # perform action1
elif <condition that evaluates to boolean>:
    # perform action2
else:
    # perform action3

```

Loops

```

my_list = [1,2,3]
my_tuple = (1,2,3)
my_list2 = [(1,2), (3,4), (5,6)]
my_dict = {'a': 1, 'b': 2, 'c': 3}

for num in my_list:
    print(num) # 1, 2, 3

for num in my_tuple:
    print(num) # 1, 2, 3

for num in my_list2:
    print(num) # (1,2), (3,4), (5,6)

for num in '123':
    print(num) # 1, 2, 3

for k,v in my_dict.items(): # Dictionary Unpacking
    print(k) # 'a', 'b', 'c'
    print(v) # 1, 2, 3

```

```

while <condition that evaluates to boolean>:
    # action
    if <condition that evaluates to boolean>:
        break # break out of while loop
    if <condition that evaluates to boolean>:
        continue # continue to the next line in the block

# waiting until user quits
msg = ''
while msg != 'quit':
    msg = input("What should I do?")
    print(msg)

```

Range

```

range(10)          # range(0, 10) --> 0 to 9
range(1,10)        # range(1, 10)
list(range(0,10,2))# [0, 2, 4, 6, 8]

```

Enumerate

```

for i, el in enumerate('helloo'):
    print(f'{i}, {el}')
# 0, h
# 1, e
# 2, l
# 3, l
# 4, o
# 5, o

```

Counter

```

from collections import Counter
colors = ['red', 'blue', 'yellow', 'blue', 'red', 'blue']
counter = Counter(colors)# Counter({'blue': 3, 'red': 2, 'yellow': 1})
counter.most_common()[0] # ('blue', 3)

```

Named Tuple

- **Tuple is an immutable and hashable list.**

- **Named tuple is its subclass with named elements.**

```
from collections import namedtuple
Point = namedtuple('Point', 'x y')
p = Point(1, y=2) # Point(x=1, y=2)
p[0]              # 1
p.x               # 1
getattr(p, 'y')   # 2
p._fields         # Or: Point._fields #('x', 'y')
```

```
from collections import namedtuple
Person = namedtuple('Person', 'name height')
person = Person('Jean-Luc', 187)
f'{person.height}' # '187'
'{p.height}'.format(p=person) # '187'
```

OrderedDict

Maintains order of insertion

```
from collections import OrderedDict
# Store each person's languages, keeping # track of who res
programmers = OrderedDict()
programmers['Tim'] = ['python', 'javascript']
programmers['Sarah'] = ['C++']
programmers['Bia'] = ['Ruby', 'Python', 'Go']

for name, langs in programmers.items():
    print(name + '-->')
    for lang in langs:
        print('\t' + lang)
```

Functions

***args and **kwargs**

Splat (*) expands a collection into positional arguments, while splatty-splat () expands a dictionary into keyword arguments.**

```
args = (1, 2)
kwargs = {'x': 3, 'y': 4, 'z': 5}
some_func(*args, **kwargs) # same as some_func(1, 2, x=3, y=4, z=5)
```

*** Inside Function Definition**

Splat combines zero or more positional arguments into a tuple, while splatty-splat combines zero or more keyword arguments into a dictionary.

```
def add(*a):
    return sum(a)

add(1, 2, 3) # 6
```

Ordering of parameters:

```
def f(*args):                # f(1, 2, 3)
def f(x, *args):             # f(1, 2, 3)
def f(*args, z):             # f(1, 2, z=3)
def f(x, *args, z):          # f(1, 2, z=3)

def f(**kwargs):             # f(x=1, y=2, z=3)
def f(x, **kwargs):          # f(x=1, y=2, z=3) | f(1, y=

def f(*args, **kwargs):      # f(x=1, y=2, z=3) | f(1, y=
def f(x, *args, **kwargs):    # f(x=1, y=2, z=3) | f(1, y=
def f(*args, y, **kwargs):    # f(x=1, y=2, z=3) | f(1, y=
def f(x, *args, z, **kwargs): # f(x=1, y=2, z=3) | f(1, y=
```

Other Uses of *

```
[* [1,2,3], *[4]]           # [1, 2, 3, 4]
{* [1,2,3], *[4]}           # {1, 2, 3, 4}
(* [1,2,3], *[4])           # (1, 2, 3, 4)
{**{'a': 1, 'b': 2}, **{'c': 3}} # {'a': 1, 'b': 2, 'c': 3}
```

```
head, *body, tail = [1,2,3,4,5]
```

Lambda

```
# lambda: <return_value>
# lambda <argument1>, <argument2>: <return_value>
```

```
# Factorial
from functools import reduce
n = 3
factorial = reduce(lambda x, y: x*y, range(1, n+1))
print(factorial) #6
```

```
# Fibonacci
fib = lambda n : n if n <= 1 else fib(n-1) + fib(n-2)
result = fib(10)
print(result) #55
```

Comprehensions

```
<list> = [i+1 for i in range(10)]           # [1, 2, ..., 10]
<set>  = {i for i in range(10) if i > 5}    # {6, 7, 8, 9}
<iter> = (i+5 for i in range(10))          # (5, 6, ..., 14)
<dict> = {i: i*2 for i in range(10)}       # {0: 0, 1: 2, ...}
```

```
output = [i+j for i in range(3) for j in range(3)] # [0, 1, 2, 3, 4, 5, 6, 7, 8]

# Is the same as:
output = []
for i in range(3):
    for j in range(3):
        output.append(i+j)
```

Ternary Condition

```
# <expression_if_true> if <condition> else <expression_if_false>

[a if a else 'zero' for a in [0, 1, 0, 3]] # ['zero', 1, 'zero', 3]
```

Map Filter Reduce

```
from functools import reduce

list(map(lambda x: x + 1, range(10)))           # [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
list(filter(lambda x: x > 5, range(10)))        # (6, 7, 8, 9, 10)
reduce(lambda acc, x: acc + x, range(10))       # 45
```

Any All

```
any([False, True, False]) # True if at least one item in collection is True
all([True, 1, 3, True])   # True if all items in collection are True
```

Closures

We have a closure in Python when:

- A nested function references a value of its enclosing function and then
- the enclosing function returns the nested function.

```
def get_multiplier(a):
    def out(b):
        return a * b
    return out
```

```
>>> multiply_by_3 = get_multiplier(3)
>>> multiply_by_3(10)
30
```

- If multiple nested functions within enclosing function reference the same value, that value gets shared.
- To dynamically access function's first free variable use
'<function>.__closure__[0].cell_contents'.

Scope

****If variable is being assigned to anywhere in the scope, it is regarded as a local variable, unless it is declared as a 'global' or a 'nonlocal'.****

```
def get_counter():
    i = 0
    def out():
        nonlocal i
        i += 1
        return i
    return out
```

```
>>> counter = get_counter()
>>> counter(), counter(), counter()
(1, 2, 3)
```

Modules

```
if __name__ == '__main__': # Runs main() if file wasn't imported
    main()
```

```
import <module_name>
from <module_name> import <function_name>
import <module_name> as m
from <module_name> import <function_name> as m_function
from <module_name> import *
```

Iterators

In this cheatsheet '**<collection>**' can also mean an iterator.

```
<iter> = iter(<collection>)
<iter> = iter(<function>, to_exclusive) # Sequence of 1
<el>   = next(<iter> [, default])      # Raises StopIteration
```

Generators

Convenient way to implement the iterator protocol.

```
def count(start, step):
    while True:
        yield start
        start += step
```

```
>>> counter = count(10, 2)
>>> next(counter), next(counter), next(counter)
(10, 12, 14)
```

Decorators

A decorator takes a function, adds some functionality and returns it.

```
@decorator_name
def function_that_gets_passed_to_decorator():
    ...
```

Debugger Example

****Decorator that prints function's name every time it gets called.****

```
from functools import wraps

def debug(func):
    @wraps(func)
    def out(*args, **kwargs):
        print(func.__name__)
        return func(*args, **kwargs)
    return out

@debug
def add(x, y):
    return x + y
```

- **Wraps is a helper decorator that copies metadata of function add() to function out().**
- **Without it 'add.__name__' would return 'out'.**

Class

User defined objects are created using the class keyword

```
class <name>:
    age = 80 # Class Object Attribute
    def __init__(self, a):
        self.a = a # Object Attribute

    @classmethod
    def get_class_name(cls):
        return cls.__name__
```

Inheritance

```
python class Person:
    def __init__(self, name, age):
        self.name = name
        self.age = age

class Employee(Person):
    def __init__(self, name, age, staff_num):
        super().__init__(name, age)
        self.staff_num = staff_num
```

```
<h2 id="multiple-inheritance">Multiple Inheritance</h2>
```python
class A: pass
class B: pass
class C(A, B): pass
```

**MRO determines the order in which parent classes are traversed when searching for a method:**

```
>>> C.mro()
[<class 'C'>, <class 'A'>, <class 'B'>, <class 'object'>]
```

## Exceptions

---

```
try:
 5/0
except ZeroDivisionError:
 print("No division by zero!")

while True:
 try:
 x = int(input('Enter your age: '))
 except ValueError:
 print('Oops! That was no valid number. Try again...')
 else: # code that depends on the try block running succe:
 print('Carry on!')
 break
```

## Raising Exception

---

```
```python raise ValueError('some error message')```
```

Finally

```
```python try: raise KeyboardInterrupt except: print('oops') finally: print('All done!')```
```

```
<h2 id="command-line-arguments">Command Line Arguments</h2>
```python
import sys
```

```
script_name = sys.argv[0]
arguments   = sys.argv[1:]
```

File IO

Opens a file and returns a corresponding file object.

```
<file> = open('<path>', mode='r', encoding=None)
```

Modes

- 'r' - Read (default).
- 'w' - Write (truncate).
- 'x' - Write or fail if the file already exists.
- 'a' - Append.
- 'w+' - Read and write (truncate).
- 'r+' - Read and write from the start.
- 'a+' - Read and write from the end.
- 't' - Text mode (default).
- 'b' - Binary mode.

File

```
<file>.seek(0) # Moves to the start of
```

```
<str/bytes> = <file>.readline() # Returns a line.
<list>      = <file>.readlines() # Returns a list of lines
```

```
<file>.write(<str/bytes>) # Writes a string or bytes
<file>.writelines(<list>) # Writes a list of strings
```

- Methods do not add or strip trailing newlines.

Read Text from File

```
def read_file(filename):
    with open(filename, encoding='utf-8') as file:
```

```
return file.readlines() # or read()
```

```
for line in read_file(filename):  
    print(line)
```

Write Text to File

```
def write_to_file(filename, text):  
    with open(filename, 'w', encoding='utf-8') as file:  
        file.write(text)
```

Append Text to File

```
def append_to_file(filename, text):  
    with open(filename, 'a', encoding='utf-8') as file:  
        file.write(text)
```

Useful Libraries

CSV

```
import csv
```

Read Rows from CSV File

```
def read_csv_file(filename):  
    with open(filename, encoding='utf-8') as file:  
        return csv.reader(file, delimiter=';')
```

Write Rows to CSV File

```
def write_to_csv_file(filename, rows):  
    with open(filename, 'w', encoding='utf-8') as file:  
        writer = csv.writer(file, delimiter=';')  
        writer.writerows(rows)
```

JSON

```
import json  
<str> = json.dumps(<object>, ensure_ascii=True, indent=1)  
<object> = json.loads(<str>)
```

Read Object from JSON File

```
def read_json_file(filename):
    with open(filename, encoding='utf-8') as file:
        return json.load(file)
```

Write Object to JSON File

```
def write_to_json_file(filename, an_object):
    with open(filename, 'w', encoding='utf-8') as file:
        json.dump(an_object, file, ensure_ascii=False, indent=4)
```

Pickle

```
import pickle
<bytes> = pickle.dumps(<object>)
<object> = pickle.loads(<bytes>)
```

Read Object from File

```
def read_pickle_file(filename):
    with open(filename, 'rb') as file:
        return pickle.load(file)
```

Write Object to File

```
def write_to_pickle_file(filename, an_object):
    with open(filename, 'wb') as file:
        pickle.dump(an_object, file)
```

Profile

Basic

```
from time import time
start_time = time() # Seconds since
...
duration = time() - start_time
```

Math

```
from math import e, pi
from math import cos, acos, sin, asin, tan, atan, degrees,
```

```
from math import log, log10, log2
from math import inf, nan, isinf, isnan
```

Statistics

```
from statistics import mean, median, variance, pvariance, stdev
```

Random

```
from random import random, randint, choice, shuffle
random() # random float between 0 and 1
randint(0, 100) # random integer between 0 and 100
random_el = choice([1,2,3,4]) # select a random element from a list
shuffle([1,2,3,4]) # shuffles a list
```

Datetime

- Module 'datetime' provides 'date' <D>, 'time' <T>, 'datetime' <DT> and 'timedelta' <TD> classes. All are immutable and hashable.
- Time and datetime can be 'aware' <a>, meaning they have defined timezone, or 'naive' <n>, meaning they don't.
- If object is naive it is presumed to be in system's timezone.

```
from datetime import date, time, datetime, timedelta
from dateutil.tz import UTC, tzlocal, gettz
```

Constructors

```
<D> = date(year, month, day)
<T> = time(hour=0, minute=0, second=0, microsecond=0, tzinfo=None)
<DT> = datetime(year, month, day, hour=0, minute=0, second=0, microsecond=0, tzinfo=None)
<TD> = timedelta(days=0, seconds=0, microseconds=0, milliseconds=0, minutes=0, hours=0, weeks=0)
```

- Use '`<D/DT>.weekday()`' to get the day of the week (Mon == 0).
- '`fold=1`' means second pass in case of time jumping back for one hour.

Now

```

<D/DTn> = D/DT.today()           # Current local
<DTn>    = DT.utcnow()            # Naive datetir
<DTa>    = DT.now(<tz>)           # Aware datetir

```

Timezone

```

<tz>     = UTC                    # UTC timezone.
<tz>     = tzlocal()              # Local timezon
<tz>     = gettz('<Cont.>/<City>') # Timezone fro

```

```

<DTa>    = <DT>.astimezone(<tz>)  # Datetime, cor
<Ta/DTa> = <T/DT>.replace(tzinfo=<tz>) # Unconverted c

```

Regex

```

import re
<str>    = re.sub(<regex>, new, text, count=0) # Substitute
<list>   = re.findall(<regex>, text)          # Returns al
<list>   = re.split(<regex>, text, maxsplit=0) # Use bracke
<Match>  = re.search(<regex>, text)           # Searches f
<Match>  = re.match(<regex>, text)           # Searches c

```

Match Object

```

<str>    = <Match>.group()          # Whole match.
<str>    = <Match>.group(1)         # Part in first bracket.
<tuple>  = <Match>.groups()         # All bracketed parts.
<int>    = <Match>.start()          # Start index of a match.
<int>    = <Match>.end()            # Exclusive end index of a matc

```

Special Sequences

Expressions below hold true for strings that contain only ASCII characters. Use capital letters for negation.

```

'\d' == '[0-9]'          # Digit
'\s' == '[\t\n\r\f\v]'  # Whitespace
'\w' == '[a-zA-Z0-9_] '  # Alphanumeric

```
